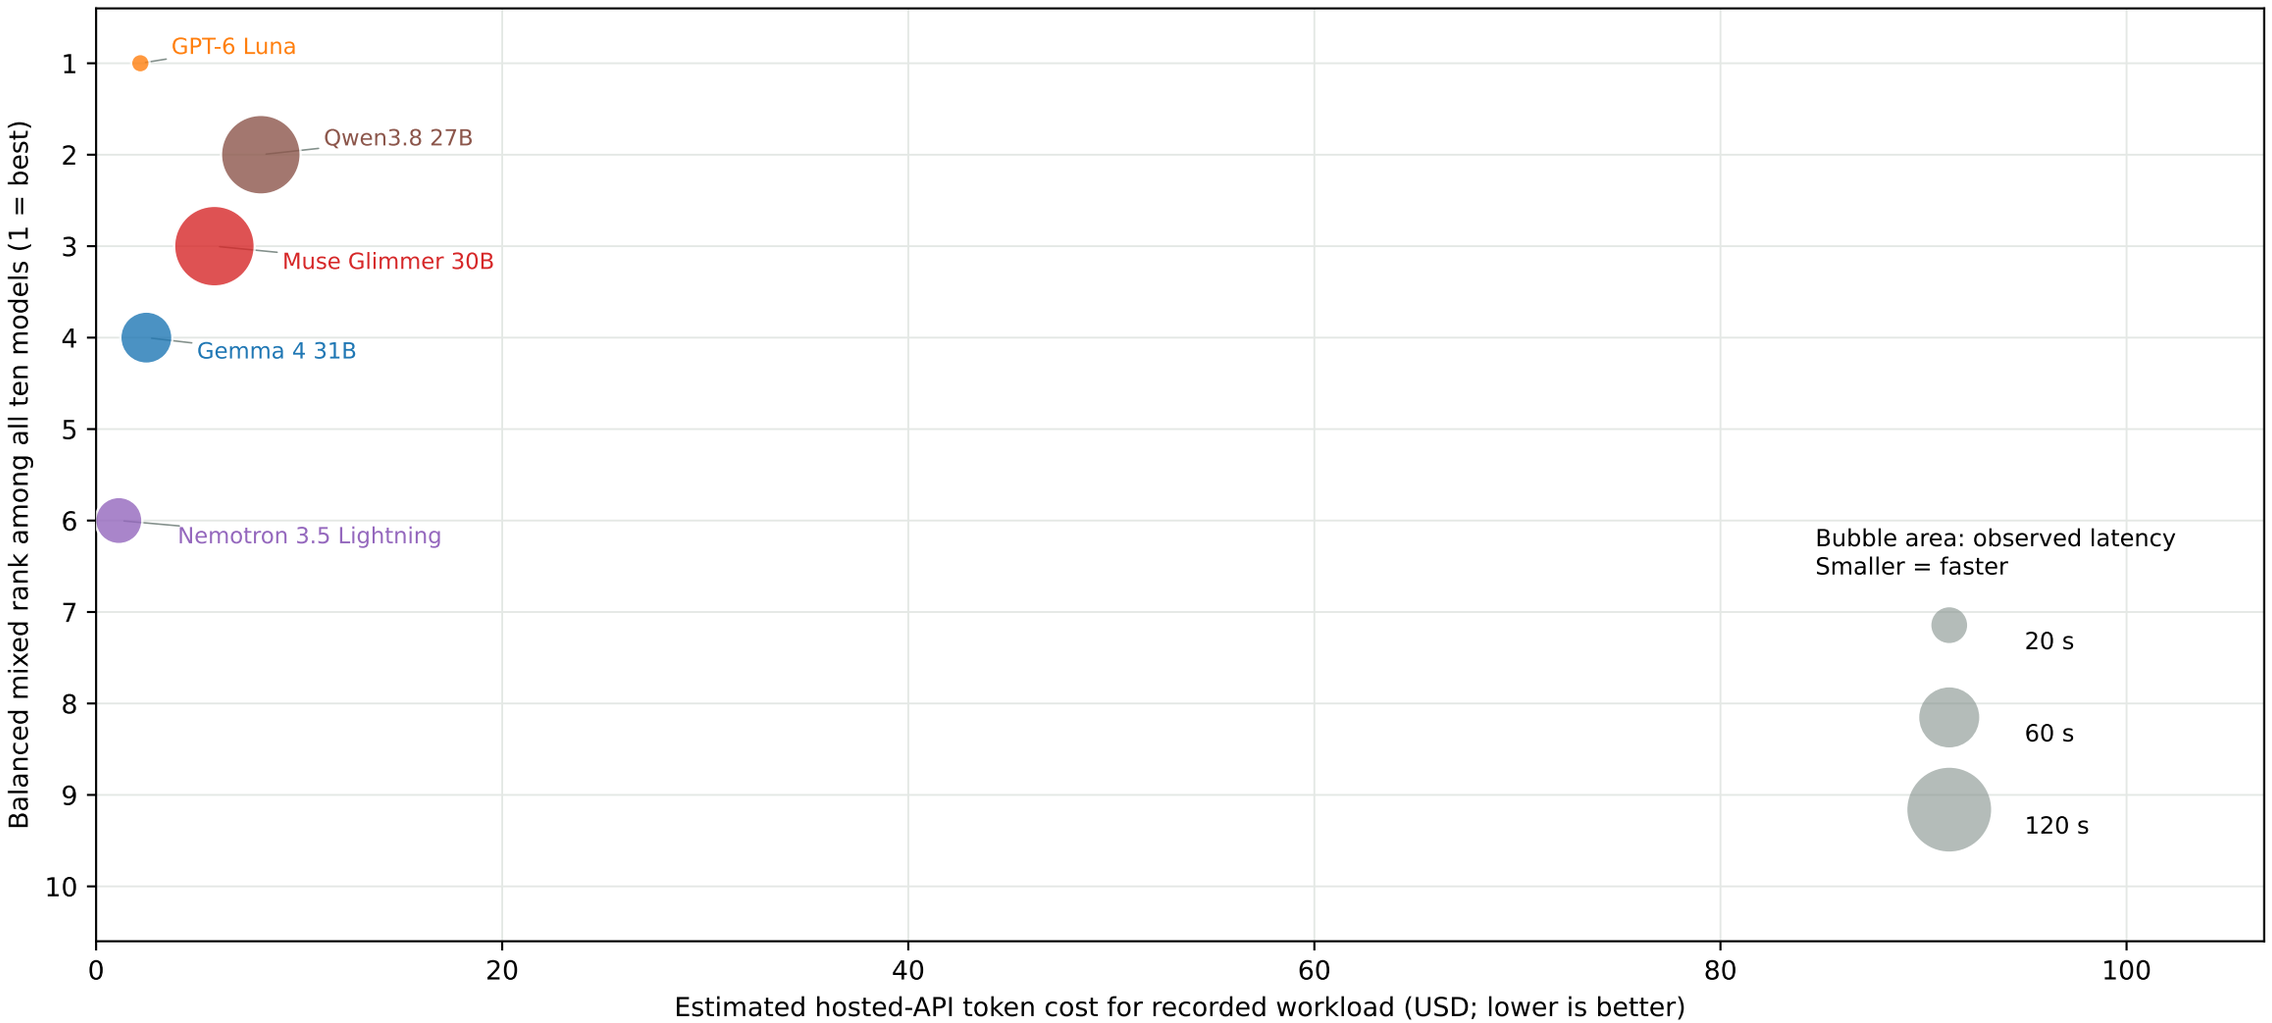
Chosen 03 | Estimated API Cost vs Mixed Rank

JRC Articles | Zero Shot | original_glm | 5/10 models priced



Upper-left with a smaller bubble is preferable. Area = 8 square points per latency second; identical area and axis scales across figures.

Cost: published hosted-API reference repricing of recorded input + output tokens, no cache discount; not actual bills.

Latency: original local/API deployments, not the priced hosted offers. Hardware, concurrency and workloads differ; cost, timing and quality are not proven row-matched.

Overall cost sums six dataset/prompt strata; overall latency averages their means equally. Ranks are retained from all ten models, not recomputed for the priced subset.

Unpriced/missing (not zero): Granite 4.2 30B, Tiny Aya Fire, Tiny Aya Global, Tiny Aya Earth, Tiny Aya Water.
